## - Contents

## Part 1 20-11-2003

## BASICS

A. Networks as complex structures
B. Fractals, Self-similarity
C. Self-organization
D. Evidence of scale-free networks
E. Basic of Graphs

> Part 3 4-12-2003
> REAL TREES
A. Food Webs
B. Geophysical data: the River Networks
C. Biological data: Taxonomy and Community Structures

## Part 2 27-11-2003

## REAL GRAPHS

A. Technological data: Internet, WWW
B. Social data: Finance and Board of Directors
C. Biological data: Proteins

$$
\text { Part } 4 \text { 11-12-2003 }
$$

MODELS
A. Random Graphs (Erdös-Renyi)
B. Small world
C. Preferential attachment
D. Fitness models

## -3A Food Webs (1)

Species and their predation relationships form a very peculiar hierarchical graph.

Top Species:
i.e. no predators

Little Rock Lake (Wisconsin) 188 species

Intermediate Species:
i.e. both predators and prey

Basal Species:
No prey

Pamlico Esthuary (North Carolina) 14 species

## -3A Food Webs (2)

A spanning tree of a connected directed graph is any of its connected directed subtrees with the same number of vertices.

In general, the same graph can have more spanning trees with different topologies.

## -3A Tree Topology (3)

Out-component size:

$$
\mathbf{A}_{\mathrm{X}}=\sum_{\mathbf{Y} \in \mathrm{nn}(\mathbf{X})} \mathbf{w}_{\mathrm{XY}} \mathbf{A}_{\mathbf{Y}}+\mathbf{1}
$$

Sum of the sizes:

$$
\mathbf{C}_{\mathbf{x}}=\sum_{\mathbf{Y} \in \gamma(\mathbf{x})} \mathbf{A}_{\mathbf{Y}}
$$

Out-component size

Allometric relations:

$$
\text { distribution } \mathbf{P ( A ) : ~}
$$ $\mathbf{C}_{\mathbf{x}}=\mathbf{C}_{\mathbf{x}}\left(\mathbf{A}_{\mathbf{x}}\right) \Rightarrow \mathbf{C}=\mathbf{C}(\mathbf{A})$

Troisieme Cycle Suisse Romande

## - 3A Allometric Relations (4)

$\mathbf{A}_{\mathbf{0}}:$ metabolic rate $\mathbf{B}$
$\mathbf{C}_{\mathbf{0}}$ : blood volume $\sim \mathbf{M}$

$$
\begin{aligned}
& \text { Kleiber's Law: } \\
& \mathbf{B}(\mathbf{M}) \propto \mathbf{M}^{3 / 4} \\
& \mathbf{C}(\mathbf{A}) \propto \mathbf{A}^{\eta} \quad \eta=\frac{4}{3}
\end{aligned}
$$

General Case (tree-like transportation system embedded in a D-dimensional metric space):
the most efficient scaling is $\mathbf{C}(\mathbf{A}) \propto \mathbf{A}^{\eta} \quad \eta=\frac{\mathbf{D}+1}{\mathbf{D}}$

## - 3A Food Webs (5)

$\delta \gg 1$

$\sqrt{6}$

$\mathbf{C}(\mathbf{A}) \propto \mathbf{A}$
efficient
$\mathbf{P}(\mathbf{A})=\delta_{\mathbf{A 1}}$
stable

$$
\mathbf{0}<\delta<\mathbf{1}
$$

$$
\delta \rightarrow \mathbf{0}
$$

$\mathbf{C}(\mathbf{A}) \propto \mathbf{A}^{\eta} \quad \mathbf{1}<\eta<\mathbf{2}$
$\mathbf{P}(\mathbf{A}) \propto \mathbf{A}^{-\tau} \quad 0<\tau<\infty$
Troisieme Cycle Suisse Romande

$\mathbf{C}(\mathbf{A}) \propto \mathbf{A}^{2}$
inefficient
$\mathbf{P}(\mathbf{A})=\cos t$ unstable

## - 3A Food Webs (6)

Results in this field are that the spanning tree of the Food web show
Some sort of optimization in resources transfer.
For this case the most efficient tree should behave like $C(A) \propto A$

Stat. Mech. of Networks-

## -3B River Network Theory (1)

Law of steepest descent produces the complex Network structure of rivers drainage basins.

## -3B River Network Theory (2)

River Networks study the interplay between Fluvial erosion and Landscape Evolution

This interplay produces "UNIVERSAL" non trivial properties.

The first quantitative measure of that universality was introduced by Hack who studied the shape of the basins.
In particular the Drainage Basins for any River on Earth display similar Fractal Properties

We investigate the statistical properties of such basins and map these Properties with the above interplay.
A possible application presented is trying to infer the presence of erosion From drainage basins of other planet (Mars).

## -3B River Network Theory (3)

Some phenomenological facts are at the basis of the River Network Theory

1. In river basins one can consider precipitation of water as nearly constant. Therefore the mass of water collected in the outlet is proportional to the area of the basin $\mathbf{A}_{i}$.
2. Water follows the steepest descent path ( $\Delta \mathbf{h}_{\mathrm{i}}$ )
3. The erosion of water modifies the landscape and can cause terrain instability. Empirically, the stable landscape are those for which

$\Delta \mathbf{h}_{\mathbf{i}} \mathbf{A}_{\mathbf{i}}^{\mathbf{0 . 5}} \mathbf{O}$ constant

## -3B Shape of Landscapes (4)

Satellite image of Himalaya Courtesy of NASA

Troisieme Cycle Suisse Romande
Stat. Mech. of Networks-

## -3B Digital Elevation Model (5)

From satellite images one gets Digital Elevation Models (DEM) From DEM a spanning tree is computed (via steepest descent) From spanning tree, the number of points uphill is computed

## -3B Statistical Measures: Hack's law (9)

$$
\mathrm{L}_{/ /} \sim \mathrm{A}^{\mathrm{h}}, \mathrm{~h} \sim 0.6
$$

This self-affinity results in power-law distributions of
-Number of points uphill
-Stream lengths

## 3B Statistical Measures: Hack's law (10)

Hack's Law

Troisieme Cycle Suisse Romande
Stat. Mech. of Networks-

## -3B Statistical Measures (11)

Different frequency distributions can be computed
-Frequency distribution $\mathbf{P}(\mathbf{n})$ to have $\mathbf{n}$ points uphill For real rivers $\mathbf{P}(\mathbf{n}) \sim \mathbf{n}^{-\tau} \mathbf{f}\left(\mathbf{n} / \mathbf{L}^{\phi}\right) \tau=1.43$ (1)
-Frequency distribution $\Pi(\mathbf{l})$ to have upstreams of length $\mathbf{I}$ For real rivers $\Pi(\mathbf{l}) \sim \mathbf{1}^{-\chi} \mathbf{g}(\mathbf{l} / \mathrm{L}) \chi=1.7$ (1)

# ALL THESE QUANTITIES ARE RELATED TO h! <br> One can describe networks by considering the $\mathbf{P ( n )}$ only 

## -3B Scaling relations (12)

For self-affine river networks

$$
\begin{aligned}
& \left.\begin{array}{l}
A^{h} \sim L_{/ /}(h>0.5) \\
L_{o} \sim L^{H}(/ H<1)
\end{array}\right\} \quad h=\frac{1}{1+H} \\
& \tau=\frac{1+2 H}{1+H}
\end{aligned} \quad \gamma=\frac{1}{1+\mathbf{H}} \quad \phi=\frac{1}{1+\mathbf{H}} .
$$

A.Maritan et al., Physical Review E 53, 1510 (1996)

## -3B Computer Simulations (13)

Computer simulations of a Self-Organised Critical model reproduce the data

Can one applies these results to other cases?

## -3B Martian Landscape (14)

Data on Mars topography were collected through the Mars Orbiter Laser Altimeter (MOLA)

## -3B Martian Landscape (15)

Computer Analysis of Warego Valley DEM from MOLA

Results are that we can distinguish regions whose DEM networks have properties similar to River Networks on Earth.

Dotted line correspond to $\mathrm{P}(\mathrm{A}) \propto \mathrm{A}^{-1.42}$

## -3C Taxonomical Trees (1)

Ecosystem $=$ Set of all living organisms and environmental properties of a restricted geographic area
we focus our attention on plants
in order to obtain a good universality of the results we have chosen a great variety of climatic environments

## -3C Taxonomical Trees (2)

Phylogenetic Tree $=$ hierarchical structure organized on different levels, called taxonomic levels, representing:

- classification and identification of different plants
- history of the evolution of different species

A phylogenetic tree already has the topological structure of a tree graph

- each node in the graph represents a different taxa (specie, genus, family, and so on). All nodes are organized on levels representing the taxonomic one
- all link are up-down directed and each one represents the belonging of a taxon to the relative upper level taxon

Connected graph without loops or double-linked nodes

## -3C Scale-free trees (3)

Degree distribution:

$$
P(k) \propto k^{-\gamma}
$$

$$
\gamma \sim 2.5 \pm 0.2
$$

The best results for the exponent value are given by ecosystems with greater number of species. For smaller networks its value can increase reaching $\gamma=2.8$ - 2.9.

Stat. Mech. of Networks-

## -3C Geographical Species subset (4)

$\gamma=2.52 \pm 0.08$

$\gamma=2.58 \pm 0.08$
Troisieme Cycle Suisse Romande
Stat. Mech. of Networks-

## -3C Random subsets (5)

In spite of some slight difference in the exponent value, a subset which represents on its own a geographical unit of living organisms still show a power-law in the connectivity distribution.

## random extraction of 100,200 and 400 species between those belonging

 to the big ecosystems and reconstruction of the phylogenetic tree

- Simulation:
$P(k)=k^{-2.6}$

## -3C Memory (6)

Particular rule to put a species in a genus, a genus in a family....? NO!
$\Longleftrightarrow P\left(k_{f}, k_{g}\right)$ that a genus with degree $k_{g}$ belongs to a family with degree $k_{f}$

- $k_{f}=1$
- $k_{f}=3$
- $k_{f}=2$
- $k_{f}=4$
$\left\langle k_{g}\right\rangle=\sum_{g} k_{g} P\left(k_{f} k_{g}\right)$
$P\left(k_{f} k_{g}\right) \propto k_{g}{ }^{-\gamma}$
fixed
$\gamma \sim 2.2 \pm 0.2$

$\Longleftrightarrow P\left(k_{o}, k_{f}\right)$ that a family with degree $k_{f}$ belongs to an order with degree $k_{o}$

- $k_{o}=1$
- $k_{o}=3$
$\left\langle k_{f}\right\rangle=\sum_{f} k_{f} P\left(k_{o}, k_{f}\right)$
- $k_{o}=2$
- $k_{o}=4$
fixed

$$
P\left(k_{o}, k_{f}\right) \propto k_{f}^{-\gamma}
$$

fixed
$\gamma \sim 1.8 \pm 0.2$

## -3C A simple model (7)

1) create $N$ species to build up an ecosystem
2) Group the different species in genus, the genus in families, then families in orders and so on realizing a phylogenetic tree

- Each species is represented by a string with $\mathbf{4 0}$ characters representing 40 properties which identify the single species (genes);
- Each character is chosen between 94 possibilities: all the characters and symbols that in the ASCII code are associated to numbers from $\mathbf{3 3}$ to $\mathbf{1 2 6}$ :

Two species are grouped in the same genus according to the extended Hamming distance $\boldsymbol{d}_{\boldsymbol{w}}$ :

$$
\begin{array}{ll}
c 1_{i}=\text { character of species } 1 & \text { with } i=1, \ldots \ldots \ldots ., 40 \\
c 2_{i}=\text { character of species } 2 & \text { with } i=1, \ldots \ldots \ldots .40 \\
& d_{E H}=\left(\sum_{i=1,40}\left|c 1_{i}-c 2_{i}\right|\right) / 40
\end{array}
$$

## -3C A simple model (8)

$$
c 1_{4}
$$

genus = average of all species belonging to it

- Same proceedings at all levels with a fixed threshold for each one
- At the last level (8) same phylum for all species (source node)

## -3C New species (9)

No correlation: species randomly created with no relationship between them
Genetic correlation: species are no more independent but descend from the same ancestor

- No correlation:

- ecosystems of 3000 species
- each character of each string is chosen at random
- quite big distance between two different species:

$$
\left\langle d_{E H}\right\rangle \sim 20
$$

## -3C New species (9)

- single species ancestor of all species in the ecosystem
- at each time step $t$ a new species appear:
- chose (randomly) one of the species already present in the ecosystem
- change one of its character
- 3000 time steps

```
natural selection
```

Environment $=$ average of all species present in the the ecosystem at each time step $t$.

- At each time step $\boldsymbol{t}$ we calculate the distance between the environment and each species:

$$
\begin{aligned}
& \left.d_{E H}<C_{s e l} \longleftrightarrow \begin{array}{l}
\text { survival } \\
d_{E H}>C_{\text {sel }}
\end{array}\right) \text { extinction }
\end{aligned}
$$

- small distance between different species:

$$
\left\langle d_{E H}\right\rangle \sim 0.5
$$

$$
P(k) \sim k^{-\gamma} \quad \gamma \sim 2.8 \pm 0.2
$$

Troisieme Cycle Suisse Romande
Stat. Mech. of Networks-

## -3C A comparison (10)

Not Correlated:

## Correlated:

Stat. Mech. of Networks-

## -3C Conclusions (11)

Results: - universality (same statistical properties for ecosystems with different number of species and climatic environment) and scale-free properties

- comparison between geographical and random subsets: evidence of the existence of a correlation between species in a same ecosystem due to some self-organizing properties
- simple model presented shows the importance of a genetic correlation

Future: - model presented is only a beginning: improvement with particular attention to environment and natural selection

- new data and chinese box ecosystem

## Applications:

- prevent correlated plants extinction due to human influence
- plant ecosystems structure and reafforestation

## -3D Models (1)

## Standard Theory of Random Graph

(Erdös and Rényi 1960)

Random Graphs are composed by starting with N vertices.
With probability $p$ two vertices are connected by an edge

Degrees are Poisson distributed

$$
P(k)=e^{-p N} \frac{(p N)^{k}}{k!}
$$

1) Growth

Every time step new nodes enter the system
2) Preferential Attachment

The probability to be connected depends on the degree $P(k) \propto k$

## Model of Growing Networks

(Barabási 1999)

Troisieme Cycle Suisse Romande

## Exploration algorithm (P. De Los Rios, T. Petermann)

Starting from a highly connected node, we move along each of its links with probability p : if a link is lost, it is lost forever.

We iterate the procedure from every reached node, and so on until there are no further links to explore.

We then consider the network of the explored links and nodes as the "measured" network.

## Exploration of a BA model

Every link is explored with probability $\mathrm{p}=0.5$
The true exponent is 3 ...
the "measured" exponent is 2.5

## An analytical derivation I

We use the lack of correlations in BA networks: a node of degree k can be connected with nodes of any other degree (i.e. of any possible age).

So, we can reformulate the exploration problem as a process evolving in parallel to the growth of the network.

1. Start from $m_{0}$ nodes, all of them "detected"
2. Add a new node, and connect it to one of the existing nodes with preferential attachment
3. This new node is "detected" if it connects to a "detected" node AND if the connection is explored (with probability p )
4. Repeat from 2. till completion

## An analytical derivation II

The total number $N(t)$ of "detected" nodes at time $t$ evolves according to the rate eq.

$$
\frac{d N(t)}{d t}=p \int_{0}^{t} \frac{d N\left(t^{\prime}\right)}{d t^{\prime}} \frac{k\left(t^{\prime}, t\right)}{2 t} d t^{\prime}
$$

# Density of detected nodes at time $t$ 

Probability to connect to a node born at time $\mathrm{t}^{\prime}$

## An analytical derivation III

We assume that $N(t)$ grows algebraically $\Rightarrow d N(t) / d t \sim t^{\alpha}$

We remember that $k\left(t^{\prime}, t\right)=\left(t / t^{\prime}\right)^{1 / 2}$
Plugging everything in the rate equation we obtain

$$
\alpha=(\boldsymbol{p}-\mathbf{1}) / \mathbf{2}
$$

## An analytical derivation IV - and last

We use the usual relation $\mathrm{P}(\mathrm{k}) \mathrm{dk}=\mathrm{dt}$, but now we modify it to $P(k) d k=d N(t)$, to obtain

$$
\begin{gathered}
\boldsymbol{P}(\boldsymbol{k}) \sim \boldsymbol{k}^{-(2+p)} \\
p=0.5 \text { implies } P(k) \sim k^{-2.5}
\end{gathered}
$$

Message: imperfect exploration changes the exponent!
